

# TLS Information Leakage: CRIME Attack

Noemi Glaeser

CMSC 8180

October 1, 2019

# Overview

## Background

- TLS

- Cookies

- Compression

## The Attack

- How it works

- Demo

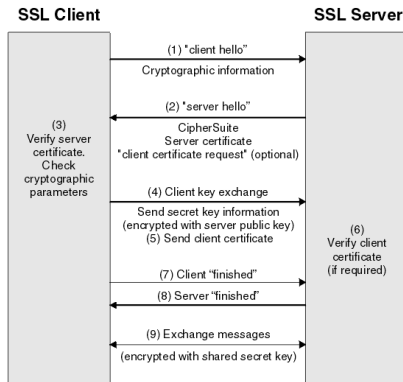

- Mitigation

## Other TLS Attacks

## Conclusion

# Transport Layer Security (TLS)

- ▶ Authenticity
  - ▶ Verify client and server identities through certificates
- ▶ Confidentiality
  - ▶ Agree on cipher suite and key

# Cookies

- ▶ Websites have no memory
- ▶ Solution: cookies
  - ▶ Small amounts of information stored on your computer by websites, e.g., session ID, login state
  - ▶ If session cookies are compromised, your session can be hijacked
- ▶ Cookies are sent in every packet header

# TLS Browser Compression

- ▶ Browsers implemented compression of packets before encryption (i.e., at the SSL/TLS level)
  - ▶ Replace repeated byte sequences with pointers

## Example

`"foobarfoo"` → `"[0]bar[0]"`  
`dict` → `[0: "foo"]`

# TLS Browser Compression

- ▶ **Idea:** If we can inject plaintext, we can use how that affects the length of the encrypted packet to guess the cookie

# TLS Browser Compression

## Example

### **Original packet:**

`"...Cookie: secret=helloworld..."`

`length = 59`

# TLS Browser Compression

## Example (Incorrect guess)

### Modified packet:

“...Cookie: secret=helloworld...Cookie: secret=x”

⇒ “...[0]helloworld...[0]x”  
length = 47

# TLS Browser Compression

## Example (Correct guess)

### Modified packet:

“...Cookie: secret=helloworld...Cookie: secret=h”

⇒ “...[0]elloworld...[0]”  
length = 45

# Compression Ratio Info-leak Made Easy (CRIME)

- ▶ Client-side attack
- ▶ **Main idea:** exploit the packet length property, which isn't hidden, using compression as an attack vector
- ▶ Guess one byte at a time and compare packet lengths
  - ▶ Can be done in 4-6 tries per byte with a binary search approach
    - ▶ Base64:  $2^6 = 64$  possible byte values
    - ▶ Hexadecimal:  $2^4 = 16$  possible byte values
- ▶ Various approaches to inject the byte guess:
  - ▶ POST body (JS with cross-site scripting attack)
  - ▶ cross-domain requests
  - ▶ insert into the query string in GET request
  - ▶ `<img>` tags
  - ▶ probably many others...

# Demo

# Mitigation

- ▶ Turn off SSL compression
  - ▶ latest browsers don't even offer it
- ▶ The usual: don't access sketchy sites or click on odd links

# Other TLS Attacks

- ▶ Browser Reconnaissance and Exfiltration via Adaptive Compression of Hypertext (BREACH)
  - ▶ Same thing but leveraging HTTP compression
- ▶ Browser Exploit Against SSL/TLS (BEAST)
  - ▶ Exploits implementation of cipher block chaining (CBC) mode in TLS 1.0
- ▶ Lucky 13
  - ▶ Timing attack

# Conclusion

- ▶ As much as stuff gets broken in real life, it's hard to break it on purpose in a specific way
- ▶ It's important to pick the right tools from the beginning
- ▶ Document your troubleshooting

# Questions?
